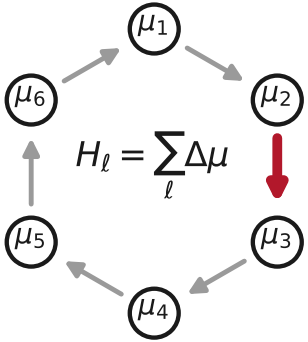
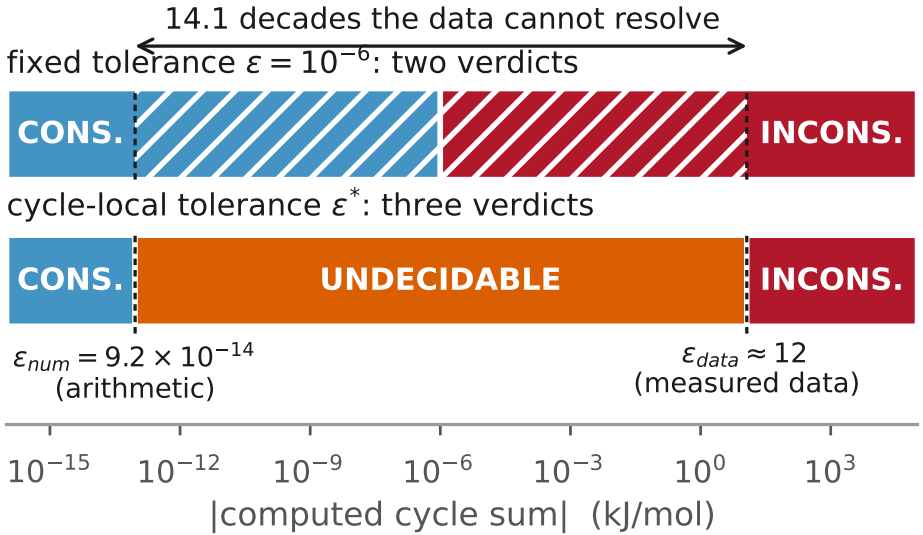
# A cycle-consistency tolerance belongs to the cycle and the data, not the solver



defect $D$

$= 0$ exactly if the edge data are a gradient. Errors on the potentials $\mu_i$ cancel; errors on an edge do not.



**67/67**

measured-data cycles flagged by $\varepsilon = 10^{-6}$

**7/67**

flagged by $\varepsilon^*$; 60 UNDECIDABLE

**0/7**

erythrocyte cycles fully measured; pyruvate kinase lies on none
